Python Scripting

Module Completion Link

Room progress (5%)

Task 1 Introduction to Python

Task 2 Hello World

To begin, let's create a simple program that outputs some text.

```
# This is an example comment
print("Hello World")
```

As you can see from the example code block above, it's just one line (shown on line 2), and when we run this code, it will output the text `hello world`. Let's break this down. In the example, line 1 is a comment, a line starting with a hashtag (#) symbol and is not run by the computer. A comment is written by the programmer (you) to help other people reading the code understand what is going on.

We can control what is output to the screen by using the `print()` statement. Anything inside of the parenthesis `()` will be output. However, because we are printing a string (more on data types later in this room), we have to put them inside of quotations `""`.

Please note, this room's examples are for Python3.

Answer the questions below

On the code editor, print "Hello World". What is the flag?

Check

?

Task 3 Mathematical Operators

Task 4 Variables and Data Types

Task 5 Logical and Boolean Operators

script.py flag.txt shipping.py bitcoin.py

Run Code

```
1 # Write your python code here
2 print("Hello World")
3
4
5
6

- String - Used for combinations of characters, such as letters or symbols
- Integer - Whole numbers
- Float - Numbers that contain decimal points or for fractions
- Boolean - Used for data that is restricted to True or False options
- List - Series of different data types stored in a collection

Title	Rating	Times Viewed	Favorite	Seen By
Star Wars	9.8	13	True	Alice, Bob
Matrix	8.5	23	False	Charlie
Indiana Jones	6.1	3	False	Daniel, Evie

Answer the questions below

In the code editor, create a variable called height and set its initial value to 200.

No answer needed ✓ Correct Answer

On a new line, add 50 to the height variable.

No answer needed Check

On another new line, print out the value of height. What is the flag that appears?

Check

Task 5 Logical and Boolean Operators

script.py flag.txt shipping.py bitcoin.py Run Code

1 # Write your python code here
2 height = 200
3 height = height + 50
4 print(height)

You can also create and write files. If you're writing to an existing file, you open the file first and use the "a" in the open function after the filename call (which stands for append). If you're writing to a new file, you use "w" (write) instead of "a". See the examples below for clarity:

```
f = open("demo1.txt", "a") # Append to an existing file
f.write("The file will include more text..")
f.close()

f = open("demo2.txt", "w") # Creating and writing to a new file
f.write("demo2 file created, with this content in!")
f.close()
```

Notice we use the close() method after writing to a file; this closes the file so no more writing to the file (within the program) can occur.

Answer the questions below

In the code editor, write Python code to read the flag.txt file. What is the flag in this file?

THM{FILE_R3AD}
